Background

- In some clinical trials, a functional test named six-minute walk test is used to measure the distinace the
- Let us assume that in a specific clinical trial, to assess the impact of physical exertion of the walk test, O after a 6-minute walk test.
- And, the results for oxygen saturation are to be reported in terms of a summary of pre-test and post-tes test saturaion level (decay) as shown below.
-

Parameter	Timepoint	Statistic	
Oxygen Saturation	Week 1, Pre-test	n	x
		Mean (SD)	xx.
Oxygen Saturation	Week 1, Post-test	n	x
		Mean (SD)	xx.
Oxygen Saturation Decay	Week 1	n	x
		Mean (SD)	xx.

Structuring the ADaM datase

- For this analysis, we need to derive the decay observered (post-test saturation minus pre-test saturatior
- There are two rules in ADaM implementation guide that govern the cases of analysis data points related
  - Rule 3: A function of one or more rows within the same parameter for the purpose of creating an ar same parameter.
  - Rule 4: A function of multiple rows within a parameter should be added as a new parameter.
- Here, as the analysis datapoint involves more than one row within same parameter but not analyzed as a

What will we learn in this lesso

- In this lesson, we will see how to derive a new parameter that follows rule 4.
