

myCSG © 2026 | Area: ADAM | Concept: C1003 : Treatment emergence, pre and post treatment occurrences | Lesson: ADAM_C1003_L201F : ADCM - Prior and concomitant medication flagging |

Lesson Description	Site SAS Program R Program
	• Clinical trials collect information on medications taken by subjects during the study. • These medications may start before treatment, during treatment, or after treatment. • For analysis, we often need to understand the timing of medications relative to study treatment. • Two common analysis flags are used for this purpose: PREFL and ONTRTFL. • PREFL identifies medications that occur before the first dose of treatment. • ONTRTFL identifies medications that occur during the treatment period. • These flags help analysts evaluate baseline medications and treatment-period medications. • Deriving these flags requires comparing medication start and end dates with treatment dates. • Real-world data may contain missing start or end dates. • Therefore, the derivation logic must also handle partial or missing date information. • In this lesson, we derive these flags and validate them against expected results for different timing scenarios.
