

myCSG © 2026 | Area: ADaM | Concept: C1001 : Subject Level Analysis Data | Lesson: ADaM_C1001_L102 : Derivation of subject level population flags which are commonly used in ADSL |

Concept Description	Lesson Description	Spec	SAS Video	SAS Program	R Program
				- For analysis purposes we may want to classify subjects based on whether they meet some prespecified criteria or not, and we create variables called population flags to indicate whether a subject meets the criteria or not. - Population flags can take either a value of Y or N. Y is used when subject is part of the specified population, otherwise N will be used. - Some commonly seen populations in clinical trial analysis are - All screened subjects - Enrolled subjects - Screen failure subjects - Randomized subjects - Safety population (Treated subjects) - Full Analysis Set population - Per-protocol population	
				In this lesson, we will see how to derive some of the key date variables and some of the regularly used population flags
