

Concept Description	Lesson Description	Spec	SAS Video	SAS Program	R Program
	Background - In a parallel arm study, subjects are randomized to one of two or more treatment arms and receive that assigned treatment for the entire duration of the treatment phase. - There are a second type of clinical trials called crossover trials in which subjects are randomly allocated to study arms where each arm consists of a sequence of two or more treatments given consecutively CDISC ADaM perspective - Even in these simpler designs, ADaM requires a structured approach to naming treatment and timing variables to ensure consistency across different study types - As these studies are a single treatment period studies, we represent the period with '01'. - We need variable to represent the planned treatment for subject in this period - we call it TRT01P - We need variable to represent the actual treatment for subject in this period - we name it as TRT01A - We need variables to represent the start and end dates of treatment - we name them TRTSDT and TRTEDT respectively.
