What is a treatment-emergent adverse event (TEAE)?

According to ICH E9, TEAE is defined as “an event that emerges during treatment, having been absent pretreatment, or worsens relative to the pretreatment state”

In other words,

An event can be called treatment-emergent if

1) If it is preexisting before treatment start but worsens in severity after treatment start

2) Absent before treatment start but occurred after treatment start.

Sometimes,

Depending on the half-life of the drug, we consider a cutoff period of 'x' days after treatment end date when deriving treatment-emergence information.

In ADaM ADAE,

We use TRTEMFL variable to capture the treatment-emergence information

The allowed values in this variable are Y and N
