Log10 Weight

Log10 Weight

- As described in the concept description, there are certain rules in ADaM implementation guide that governs on when to add derived rows as a new parameter.
- In this lesson, we will see a scenario where new parameter has to be added based on rule 2.
- We have weight of the subjects collected over time, and let us assume that the analysis value of interest is the change from baseline in log10 transformed values of weight
 - that is, we need: $\log_{10}(\text{result}) - \log_{10}(\text{baseline})$
- For this, we need to transform the result and baseline result to apply log10 function to calculate the log transformed change.
- As per rule 1 which governs the creation of new variables, if no transformation is needed on avar or base, we could add the derived information as a new variable.
- As we need transformation of base here, we cannot apply rule 1 and hence add new parameter based on rule 2.
- So, we are creating a new set of rows with a different parameter name to store the log transformed values
