- As part of vital signs dataset, we have the height of the subjects collected at screening
- And, weight collected over different time points
- For analysis purposes, let us assumme that we want to summarize the changes in BMI
- BMI is a function of Height and Weight and can be calculated as [Weight (kg)/Height (m)*Height (m)]
- As per ADaM standard, when analysis result required is a function of two or more parameters, then new set of rows have to created with a new parameter name.
