

Background

- Let us say we have a TFL shell which summarizes the result and change from baseline at each visit and 'Minimum value postbaseline' is considered as 'conceptual' analysis timepoints in the shell provided to U

		Result	
	n	Mean	SD
Baseline	xx	xx.x	xx.xx
Week 2	xx	xx.x	xx.xx
Week 4	xx	xx.x	xx.xx
Week 8	xx	xx.x	xx.xx
Week 24	xx	xx.x	xx.xx
Minimum value postbaseline	xx	xx.x	xx.xx

Structuring the ADaM data

- For the derived datasets to be analysis-ready, we need to identify the minimum value observed during postbaseline period and add that record to parent dataset.
- In ADaM implementation guide, there are certain rules that guide a user on when to add an analysis dataset.
- Rule 3: A function of one or more rows within the same parameter for the purpose of creating an analysis dataset.
- 'Minimum value postbaseline' is considered as 'conceptual' analysis timepoints in the shell provided to U
- So, we need to apply 'Rule 3' for this scenario and add new rows for the same parameter in this scenario.

What will we learn in this lesson

In this lesson, we will see:

- How to identify the record with minimum value and append that record to parent dataset
- Usage of 'DTYPE' variable to identify the derived records.
