

Lesson Description	Site	SAS Program	R Program
			• In clinical trials, typically we use the last assessment on or before treatment start date as the baseline value • In some of the previous lessons, we have seen cases where alternate definitions of baseline may be required like ◦ Minimum value seen during screening ◦ Maximum value seen during screening ◦ Average value seen during screening etc. • There can be cases where data is collected over different timepoints within a visit like [pre-dose, 30 min post-dose at each visit], [8 am, 12 am, 2pm on the day of treatment start and at the same timepoints over subsequent visits] • We may want to compare the results at postbaseline visits with the matched timepoints collected on the baseline visit ◦ pre-dose result on baseline visit is compared with pre-dose value at postbaseline visit ◦ 8 am result is compared with 8 am result at postbaseline visit, and same case of other timepoints. • From ADaM perspective, we may call this as timepoint matched baseline • As the definition of baseline at each timepoint is different, we will have to make use of the rule 6 of ADaM IG ◦ Rule 6. When there is more than one definition of baseline, each additional definition of baseline requires the creation of a set of its own rows.
