

Background

- In clinical trial data, there will be cases where multiple collections are present in an analysis visit
- In those scenarios, we get a question on which record to choose from the available records for by visit analysis (for by visit analysis only one record should be considered for a subject and parameter)
- A predefined rule is generally specified in the statistical plan on which of those records to use
- One such rule is to use the record which is closest to target day and if multiple records exists which are equally close then to use the earliest one
- We populate an analysis flag as 'Y' on tho chosen record.

Subject	Parameter	Visit	Collection day	Target day	How far from target?
1001	SYSBP	Week 2	13	14	1
1001	SYSBP	Week 2	15	14	1

What is covered in this lesson

In this lesson,

- We will see how to identify the record which is closest to the target day
- Identify the earliest record when multiple records exist which are equally close to the target
- Populate analysis flag on the chosen record
