Background for criteria flags

- In clinical trial data analysis, we will often be interested in checking if the collected result meets a predetermined condition
- We should be able to tell if the condition is met or not met
- One approach is to create a new variable and populate it with a value of Y when condition is met, and use a value of N when the condition is not met
- We may also want to capture the condition that we are testing in a separate variable

ADaM implementation

- CDISC ADaM standard allows for such type of analysis requirement and has standard variables for this purpose
- We have CRITy and CRITyFL variables to capture the related information
- CRITy variables have to be used to populate with a concise description of the condition being tested
- CRITyFL variables have to be used to populate with Y when the condition is met, and with N when the condition is not met
