Concept Description	Spec	SAS Video	SAS Program	R Program
Predefined Analysis Criteria				
- For analysis purposes, we may want to check if a record meets a predefined criteria - Some examples of predefine criteria: - Is systolic blood pressure greater than 160 mmHg - Is a liver function test parameter result exceeded more than five times the upper limit of normal range - Did the diastolic blood pressure increase by value of 25 points when compared to baseline value of the subject - There can be cases where we are interested in just knowing whether the condition is met - There can be cases where we are interested in number of records which did not meet the criteria along the number of records which meet the condition				
ADaM Implementation				
- ADaM has a variable pair CRITy/CRITyFL to support this case of checking for predefined criteria - CRITy is used to store the text description of the criteria being checked for - CRITyFL - criterion evaluation result flag - is used to indicate whether the criteria described in CRITy is met or not
