Background

The typical flow of a participant in clinical trial is to

- provide consent to participate in the study - **informed consent**
- undergo screening procedures
- be assigned to one of the treatment groups of the study - **randomization**
- get treated for the specified period - **end of treatment**
- followed up for certain period post treatment completion
- end the study - **end of study**
- Data is collected in case report forms to account a subject for all the above steps
- Data related to informed consent, randomization to study treatment is typically called as 'protocol milestones'
- Data related to the completion/discontinuation status of treatment or study is called as 'disposition event'
- Disposition (DS) dataset is used to provide an accounting for all subjects who entered the study in terms of protocol milestones and disposition events.

What will we learn in this lesson

- We will see how to program SDTM.DS dataset for a hypothetical study
