Background
• In clinical trials, when taking a drug or investigational product, the trial participant (subject) may experience some medical occurrences along with the intended effect of the drug. • Some of these medical occurrences could be untoward or unintended and we call those untoward events as 'adverse events'. • Some of the medical occurrences could be of specific interest within the context of a study and such occurrences which cannot be classed as 'adverse events' are called 'clinical events' • The occurrences which cannot be classed as 'adverse events' will be specified in the study protocol • Some examples of medical occurrences which could be classed as 'clinical events' ◦ Decreased blood glucose levels (hypoglycemia) in a study examining the treatment of controlling blood glucose in the treatment of diabetes ◦ Headache in a study examining new treatment options for migraine ◦ Seizures in an epilepsy study ◦ Fever in a vaccine study ◦ Pain at the site of injection in an injectible vaccine study • In most cases, we collect information on whether specific event of interest occurred or not, and additional information when it occurred • The additional information collected about the event will be reported in FA domain.
What type of information is typically collected or presented?
• Term described by the subject to explain the event • Standardized term for the event • Did the event occur? ◦ No ◦ Yes ▪ Start date/time of the event ▪ Status of the event - ongoing or ended? ▪ If ended, end date/time of the event ◦ Information not collected ▪ Reason for non-collection • Severity/intensity of the event
