

Lesson Description	SAS Video	SAS Program	R Program	Data 2025.05.26 21.28.50
				• In this lesson, we will see how to create a macro to populate baseline flag and related baseline variables in ADaM BDS datasets • The overall flow of baseline flag and baseline variable derivation is: ◦ Subset the qualifying records ◦ Pick the required record ◦ Flag ABLFL as Y on the record that is identified as baseline record ◦ Populate the baseline variables using the results from baseline record on all the records of a subject and parameter • Name of the macro is : adam_create_ablfl_basevars • Macro variables: ◦ indsn=name of the input dataset ◦ outdsn= name of the output dataset ◦ filtercondition=filter condition to use in a where statement to select qualifying records for baseline ◦ byvars=list of variables to be used for sorting the records based on baseline flag definition such that required record comes at the end ◦ lastdot=name of the variable to use in if statement with last.<variable> ◦ sourcevars=list of variables whose values have to be used as baseline values (eg: AVAL, AVALC, ANRIND etc) ◦ basevars=list of new variable names to capture the baseline values (eg: BASE for AVAL, BASEC for AVALC) etc. • We will make use of adam_make_date_time to create numeric date variable
