

Background

- This lesson is an extension of [L2031](#)
- When reviewing ADSL dataset, we may want to programmatically verify if the variables are derived correctly from source datasets
- For some variables, the derivation may involve selecting a specific record from the source dataset — such as the first or last occurrence — based on a sort order
- In other cases, we may need to apply transformations, compute new variables, or carry forward specific values from the source dataset
- So, we need a flexible way to fetch and process records from one or more source datasets, with each dataset potentially appearing more than once with different filter conditions
- We can then merge these processed subject-level datasets against ADSL to quickly verify if the derived variables are correct

What is covered in this lesson

- In this lesson, we will see a framework that can be quickly updated to derive variables in ADSL
