

Background

- When creating SDTM datasets from collected data of a clinical trial, we typically convert the collected data values into standard terminology
- In this lesson, we will see some theoritical examples of such conversions
- We will see an example of conversion of the numeric coded values to text description
- We will see an example of conversion of abbreviated text values to fully expanded text values
- We will see an example of text case conversion
- We will also see an example programming approach on how to make use of standard metadata maintained by sponsors

SAS programming concepts involved

- Creation of a user defined format using proc format and usage of it on put function
- Usage of text case conversion function
- Usage of data step merge feature to fetch matched values from a second dataset
- Creation of new variables using conditional logic - if then else

R programming concepts involved

- Usage of rename function to rename the input variables
- Replication of the concept of user-defined format using named vector
- Usage of a text case conversion function
- Replication of the concept of conditional logic using case_when function
- Replicaton of the concept of joining datasets to fetch matched values from a second dataset
