

Background

- SDTM.DM domain is used to capture some important demographics related variables and certain key date variables for the subject
- RFPENDTC is one such date variable
- It is used to capture the 'Date/Time of End of Participation' of a subject
- At the end of the study, this will be equivalent to the end of study date for the subject when the subject discontinued/completed the study
- This variable will generally be used in downstream ADaM programming to identify the last known date of subject on study
- Some specification authors prefer keeping it equivalent to the end of study date (from a disposition page), while others prefer deriving it based on all applicable date variables in study
- If the first approach is used, the 'last known date' will be derived in ADaM datasets using all applicable date variables from SDTM datasets

What do we learn in this lesson?

- In this lesson, we will see a programming approach to derive RFPENDTC variable using applicable raw date variables

Visualization

SUBJECT	Date	SUBJECT	Date	SUBJECT	Date	SUBJECT	Date1	Date2

- We have different datasets with a one or more date variables
- In order to get the latest date for each subject from all these variables, it will be easy if we have all of the values in a single variable as shown below

[illegible]

- So, we pull all dates into a single dataset and then find the latest date for each subject to populate RFPENDTC
