

Lesson Description	SAS Video	SAS Program	R Video	R Program
Background We have seen in supplementary dataset creation that: • SDTM standard has standard domains • Each standard domain is based on a class – findings, events, interventions • Each class has a set of variables that are allowed to be used in an SDTM dataset that is based on that class • Other variables are not allowed to be kept in the dataset • As part of clinical trial needs, there can be data points that are needed for the study but there is no standard variable to map the information to • The variables that are used to store the information that cannot be mapped to standard variables are called non-standard variables • SDTM allows to store the information from these non-standard variables into a dataset called 'supplementary dataset' of that domain • Each value in these non-standard variables is linked to the record in parent domain by an identifier variable (like --SEQ, --GRPID, --REFID etc) • The information in these non-standard variables are presented as rows in the supplementary data, one row for each non-missing result of each non-standard variable • So, the structure of the supplementary dataset is 'One record per IDVAR, IDVARVAL, and QNAM value per subject' • When working on data analysis, we want to bring back the QNAMs from the supplementary datasets into parent domains as variables What will we learn in this lesson? In this lesson, we will see how to merge the supplementary dataset to parent dataset
