

Background
- Each software will typically create files with their proprietary file extensions - These files with proprietary extensions may not be easily accessible in other softwares - If government agencies like US FDA accept file types/formats that are of specific software (vendor), there will be an undue advantage for that vendor - So, government agencies generally prefer vendor neutral or standards that are openly accessible - SAS V5 Transport (XPT) format standard is one such openly accessible data format - XPT files are software-agnostic and can be opened in various statistical tools, ensuring consistent data access across different platforms (like R, SPSS etc) - So, the SDTM and ADaM datasets we submit to FDA are converted to xpt files
What will we learn in this lesson?
create xpt files using xport engine of libname statement and proc copy
